# Administrative Data in Foster Care: An Aggregate Approach

## Administrative Data in Foster Care: *An Aggregate Approach*

John Thomas Halloran  
Lewis University— jhalloran2@lewisu.edu  
Chapin Hall Center for Children  
Center for State Child Welfare Data

## Principles of the foster care system and structure of administrative foster care data

- › Foster care is a state intervention to provide care for children who cannot be housed in the home of their parents (typically for reasons of abuse and neglect).
- › At any given time there are approximately 400,000 children in foster care (AFCARS, 2016).
- › Agencies responsible for these interventions track, in minute detail on a case level and daily basis, placements, services, and other activities for each foster placement.
  - › *Risk management*
  - › *Reimbursement*
  - › *Caseload management*

University of Chicago

Center for State Child Welfare Data

## Entries and Exits

- › Children are placed in foster care (*Enter*); stay for some period of time; and then are released from foster care (*Exit*).
- › Nationally, in FY2015 (AFCARS, 2016):
  - › 269,509 children entered care
  - › 243,060 children exited care
  - › A point in time count found 427,910 children in care
  - › Considerable churn in these populations
- › The period of placement in foster care between an entry and an exit is referred to as a “*spell*.”

Center for State Child Welfare Data

## Population-based analysis

- The tendency toward individual-level explanations of social phenomena may veil important population-level dynamics.
- Is the behavior (or to what degree is the behavior) of the population reducible to individual-level decisions?
- Are there properties of the population which are not easily explained by aggregating individuals?
- What can population-based analysis reveal about structures which bound individual-level decisions?

## Modeling systems through coupled difference equations with annotations

X is the number of entries/admissions; Y is the number of exits/discharges

Future state of variable  
(dynamic time series analysis)

Functional relationship between present  
state of variable and future state of variable

$$\begin{aligned} X(t+1) &= X(t)[r_x - r_x X(t) - \beta_{x,y} Y(t)] \\ Y(t+1) &= Y(t)[r_y - r_y Y(t) - \beta_{y,x} X(t)] \end{aligned}$$

Rate parameter

Capacity parameter

Coupling: the  $x$  variable  
occurs in the  $y$  equation  
(and vice versa)

Center for State Child Welfare Data

## Capacity and Resource Dependence: An Example from Congregate Care

- › Congregate care is a type of foster care where children are placed in a group setting.
- › Resources in congregate care are relatively inelastic in relation to demand over the short term
  - › It takes time and money to put a bed on line
  - › Fixed costs in built, institutional settings
  - › This inelasticity may produce capacity constraints
  - › Staffing levels must be maintained
  - › Buildings cost money to maintain and operate
- › We can expect to see these constraints manifest themselves within the dynamics of a time series.

## Linear Patterning of the System through Lags

- Can we see structure in the aggregate population dynamics?
- CC lags compared to more weakly coupled/null systems

Chapin Hall Center for Children  
Center for State Child Welfare Data

## Convergent Cross Mapping: State-Level Congregate Care

- Entries cause exits: 0.7979  
( $p < .001$ )
- Exits cause entries: 0.7660  
( $p < .001$ )

## What does this structure tell us?

- Rate of response of a system to stimuli. *Resilience?*
- Existence of capacity constraints within system. *Resources?*
- *Potentially*: Difference between individual- and population-level dynamics. *Policy v. practice?*
- *Potentially*: Short-term forecasting. *Planning?*
- *Potentially*: Opportunities to back findings into parametric models. *Integration?*
